
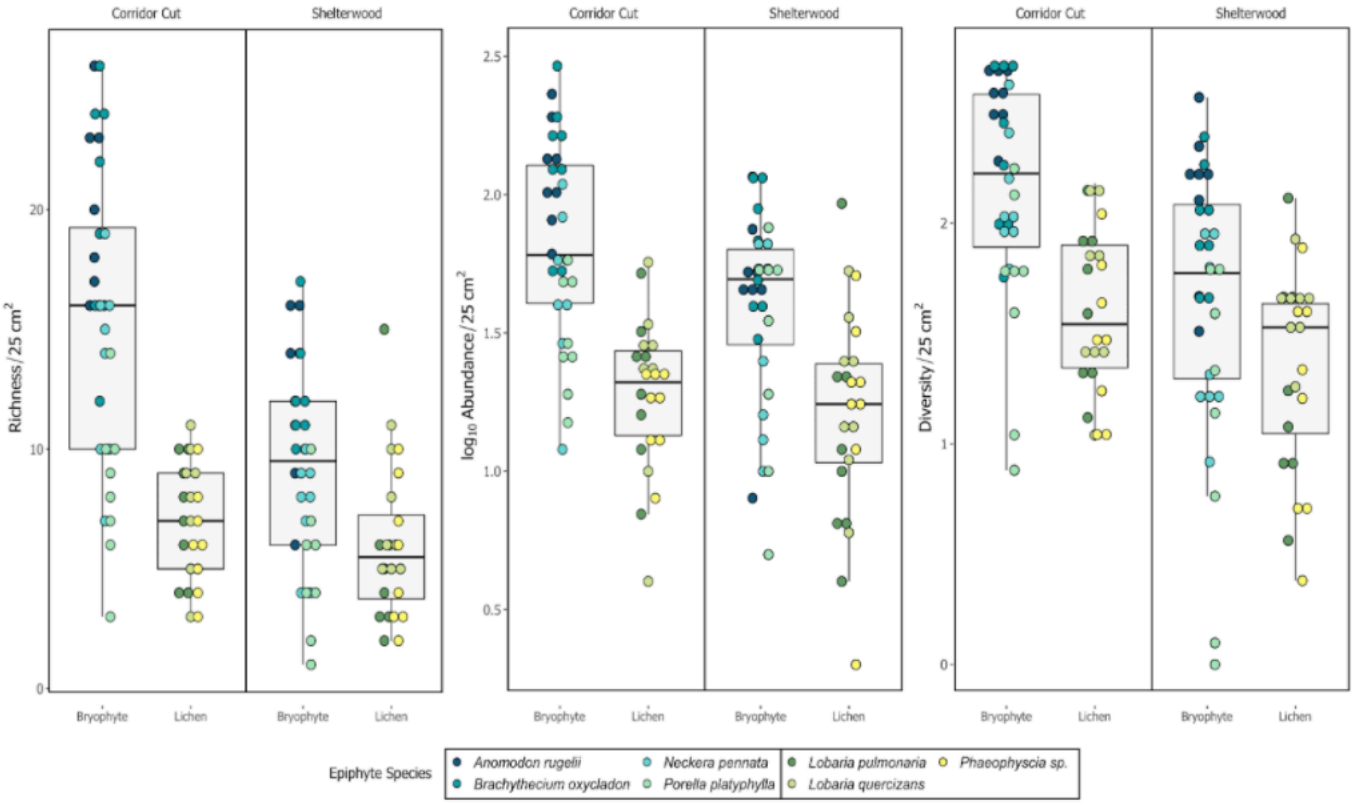

Figure 2. Richness, abundance, and Shannon-Weiner diversity index of microarthropods per 25 cm^2 epiphyte sample. Arthropods were extracted from eight samples of each of the four bryophyte species, n=32, and three lichen species, n=24, and sorted to family-level resolution. Boxplots are separated by treatment type, with corridor cut reserve on the left and shelterwood on the right of each plot. Within treatments, the two boxplots represent epiphyte type, with bryophytes on the left and lichens on the right. The central horizontal line within the boxes represents the median value, with the upper and lower limits representing the third and first quartile, respectively. The vertical lines represent the range of normally distributed data, Q3+1.5xIQR to Q1-1.5xIQR. A dotplot is overlaid onto each boxplot to display the distribution of data by species of bryophyte or lichen in each of the treatments. Abundance data have been $\log_{10}$ transformed in order to more appropriately distribute these data across epiphyte species.
